Self-Consistent Description

Electric Field → 2-Level Atom

We need to set up and solve a set of workable simultaneous equations for the atoms and field.

(1) The electric field. We write

$$\vec{E}(2,t) = \vec{E}E(2,t)e^{-i(\omega t - k2)}$$
wavepacket envelope

Plane wave propagating in the +2 direction,
 the real part is the physical field

Slowly Varying Envelope Approximation (SVEA)

We require that the envelope $\mathcal{E}(\mathcal{L}_{i}\mathcal{L})$ is smooth in space and time compared to the plane wave part.

This is not particularly restrictive, unless working with ultrafast lasers.

(2) The Macroscopic Polarization Density.

We use the quantum expectation value デュル = N(ネ)

Of this, we need the complex part that goes with $\mathbf{E}(\mathbf{l}_{i}\mathbf{t})$ and can be plugged into the wave equation.

Thus, of

$$\langle \vec{\eta} \rangle = \vec{\eta}_{12} \langle a_1 a_1^* \rangle + \vec{\eta}_{21} \langle a_1 a_2^* \rangle$$

$$= \vec{\eta}_{12} \mathcal{S}_{21} e^{-i(\omega t - k_2)} + \vec{\eta}_{21} \mathcal{S}_{12} e^{i(\omega t - k_2)}$$
slow variables

we need the part that goes as $e^{-i(\omega_t - le_t)}$

The physical field is $\text{Re}\left[\vec{E}\left\{(\frac{1}{2},t)e^{-i(\omega t - \frac{1}{2})}\right\}\right]$ The physical dipole is

$$\operatorname{Re}\left[\vec{\eta}_{12}S_{2i}e^{-i(\omega t - k_2)} + \vec{\eta}_{2i}S_{12}e^{i(\omega t - k_2)}\right]$$
Note factor of $2 \Rightarrow = 2 \times \operatorname{Re}\left[\vec{\eta}_{12}S_{2i}e^{-i(\omega t - k_2)}\right]$

Note: The coherence S_{l_l} depends on E_l because the field depends E_l through the field envelope E_l implicit SVEA on S_{l_l} .

Note: In a real, multilevel atom need not be parallel to the field. However, only the part that is parallel to the field can emit radiation that interferes with it and lead to absorption and dispersion.

The complex dipole parallel to \vec{z} is

$$\vec{P}(\xi, t) = \vec{E} 2N (\vec{\eta}_{12} \cdot \vec{E}^{*}) g_{11}(\xi_{1}t) e^{-i(\omega_{1} - k_{2})}$$

$$\equiv \vec{E} 2N \mu^{*} g_{21}(\xi_{1}t) e^{-i(\omega_{1} - k_{2})}$$

Note: Because of the RWA we have

$$\left|\frac{\partial \xi}{\partial S^{2}}\right| \ll \omega \left|S^{2}\right| \qquad \left|\frac{\partial \xi}{\partial S^{2}}\right| \ll \omega \left|\frac{\partial \xi}{\partial S^{2}}\right|$$

$$(|\mathcal{E} \times \mathcal{E}|)| \eta \rangle \Rightarrow \vec{\eta}_{12}^{u} = (\mathcal{E}_{\eta}^{\times})(\mathcal{E}_{x}^{*}, \mathcal{E}_{y}^{*}) \left(\frac{\eta_{12}^{(x)}}{\eta_{12}^{(y)}} \right) = \vec{\mathcal{E}}(\vec{\eta}_{12} \cdot \vec{\mathcal{E}}^{*})$$

Milloni & Eberly notation

Thus, of

$$\langle \vec{\eta} \rangle = \vec{\eta}_{12} \langle a_1 a_1^* \rangle + \vec{\eta}_{21} \langle a_1 a_2^* \rangle$$

$$= \vec{\eta}_{12} \, \mathcal{S}_{21} e^{-i(\omega t - k_2)} + \vec{\eta}_{21} \mathcal{S}_{12} e^{i(\omega t - k_2)}$$
slow variables

we need the part that goes as $e^{-i(\omega_t - k_t)}$

The physical field is $\text{Re}[\vec{E}[t,t]e^{-i(\omega t - kt)}]$ The physical dipole is

$$Re[\vec{\eta}_{12}S_{2i}e^{-i(\omega t - k_2)} + \vec{\eta}_{2i}S_{12}e^{i(\omega t - k_2)}]$$
Note factor of 2 \Rightarrow = $2 \times Re[\vec{\eta}_{12}S_{2i}e^{-i(\omega t - k_2)}]$

Note: The coherence $S_{i,t}$ depends on $\overline{c}_{i,t}$ because the field depends $\overline{c}_{i,t}$ through the field envelope $\underline{c}(2,t)$ implicit SVEA on $S_{i,t}$.

Note: In a real, multilevel atom need not be parallel to the field. However, only the part that is parallel to the field can emit radiation that interferes with it and lead to absorption and dispersion.

The complex dipole parallel to \vec{z} is

$$\vec{p}(t,t) = \vec{\epsilon} 2N (\vec{\eta}_{12} \cdot \vec{\epsilon}^*) g_{11}(t+1) e^{-i(\omega t - k_2)}$$

$$\equiv \vec{\epsilon} 2N \mu^* g_{21}(t+1) e^{-i(\omega t - k_2)}$$

Note: Because of the RWA we have

$$\left|\frac{\partial g_{ij}}{\partial t}\right| \ll \omega \left|g_{2i}\right| \qquad \left|\frac{\partial t^2}{\partial t^2}\right| \ll \omega \left|\frac{\partial f_{2i}}{\partial t}\right|$$

(3) Maxwells eqs. | Wave Equation

$$\left(\frac{\partial^2}{\partial t^2} - \frac{1}{C^2}\frac{\partial^2}{\partial t^2}\right) \vec{E}(t,t) = \frac{1}{\xi_0 C^2} \frac{\partial^2}{\partial t^2} \vec{p}(t,t)$$

We plug in the complex $\overrightarrow{E}(\mbox{ξ},\mbox{ξ})$ and $\overrightarrow{P}(\mbox{ξ},\mbox{ξ})$, use the SVEA conditions on the derivatives to eliminate all but the leading terms, and finally take the scalar product with $\mbox{$\xi$}$ to get a scalar equation. (Home Work Problem)

This gives us our final equation for the envelope:

$$\left(\frac{\partial}{\partial z} + \frac{1}{C}\frac{\partial}{\partial t}\right) \mathcal{E}(z,t) = \frac{il_{e}}{e_{e}} N_{u} \mathcal{E}_{l}(z,t)$$
where $u^{*} = \vec{\eta}_{12} \cdot \vec{\epsilon}^{*}$

Write \S_{Σ_I} in terms of the Bloch variables to get the

Maxwell-Bloch Equations

Note: The Maxwell-Bloch Equations are a key result. They lead to rich physics, including absorption, gain, dispersion, self-induced transparency, solitons, lasers, and much more.

Steady-State Solutions to MBE's

Steady state means that

$$\frac{1}{c}\frac{\partial \mathcal{E}}{\partial t} = 0 \quad \& \quad \mathcal{G}_{2l}(\mathcal{L}_{l}t) \Rightarrow \mathcal{G}_{2l}(\infty) = \frac{-i\chi/2}{\beta + i\Delta} \left(\mathcal{G}_{22} - \mathcal{G}_{11}\right)$$

Combine with $\chi = \sqrt{2} \cdot \vec{z} \cdot \vec{z} = m \cdot \vec{z} / \vec{z}$

$$\frac{\partial \mathcal{E}}{\partial z} = \frac{i \ell_0}{\epsilon_0} N_{\mu}^* \left(\frac{-i \mu \mathcal{E}}{2 \ell_0} \right) \frac{1}{\beta + i \Delta} (g_{22} - g_{\mu})$$

$$= \frac{\ell_0 N_{\mu}^2}{2 \ell_0 \epsilon_0} \frac{\beta - i \Delta}{\Delta^2 + \beta^2} (g_{22} - g_{\mu}) \mathcal{E}$$

We can rewrite this as

$$\frac{\partial \mathcal{E}}{\partial z} = \frac{1}{2} (\alpha - i\delta) \mathcal{W} \mathcal{E}$$

$$\alpha = \frac{k N |\mathcal{M}|^2}{2 \mathcal{L} \mathcal{E}_o} \frac{\mathcal{B}}{\Delta^2 + \beta^2} = N \sigma(\Delta)$$

$$\delta = \frac{k N |\mathcal{M}|^2}{2 \mathcal{L} \mathcal{E}_o} \frac{\Delta}{\Delta^2 + \beta^2} = N \frac{\Delta}{\mathcal{B}} \sigma(\Delta)$$

To compare with our classical theory of dispersion, we solve for $\mathcal{L}(2)$ and plug into eq. for a plane wave.

Envelope:
$$\mathcal{E}(2) = \mathcal{E}_0 e^{\left(\frac{\Omega \omega}{2}\right)^2} e^{i\left(-\frac{2\omega}{2}\right)^2}$$

Real & Imaginary Index of Refraction

$$N_{T} = -\frac{\alpha \omega}{2k} = -\frac{N\omega}{2k} \sigma(\Delta)$$

$$N_{R} = 1 - \frac{\delta \omega}{2k} = 1 - \frac{\Delta}{3} \frac{N\omega}{2k} \sigma(\Delta)$$

Analogous to results from Electron Oscillator

$$N_{\pm}(\omega) = \frac{Ne^2}{4 \xi_p m_e \omega} \frac{\beta}{\Delta^2 + \beta^2}, \quad N_{R}(\omega) = \frac{\Delta}{\beta} N_{\pm}(\omega)$$

Behavior of the Intensity

$$\frac{\partial}{\partial z} [\mathbf{z}^* \mathbf{E}] = \mathbf{E}^* \frac{\partial \mathbf{E}}{\partial z} + \frac{\partial \mathbf{E}^*}{\partial z} \mathbf{E}$$

$$= \frac{1}{2} (\mathbf{a} - i\mathbf{d}) \mathbf{w} [\mathbf{E}]^2 + \frac{1}{2} (\mathbf{a} + i\mathbf{d}) \mathbf{w} [\mathbf{E}]^2 = \mathbf{a} \mathbf{w} [\mathbf{E}]^2$$

$$\frac{\partial I}{\partial z} = \alpha w I = \alpha (g_{21} - g_{11}) I$$

Note that
$$\begin{cases} a = NG(\Delta) \ge 0 \\ T(2) = T(0) e^{a(921-9n)} \ge 0 \end{cases}$$

Exp. Decay of
$$T$$
 for ς_{22} ς_{11} $\lt \delta$

Exp. growth of
$$\mathbf{I}$$
 for $\mathbf{S}_{22} \mathbf{S}_{11} > 0$

must be maintained by some external process

Behavior of the Dispersion:

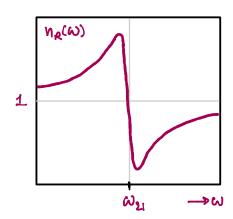

Real & Imaginary Index of Refraction

$$N_{T} = -\frac{\Omega \omega}{2k} = -\frac{N\omega}{2k} \sigma(\Delta)$$

$$N_{R} = 1 - \frac{\delta \omega}{2k} = 1 - \frac{\Delta}{C} \frac{N\omega}{2k} \sigma(\Delta)$$

$$N_R = 1 - \frac{\delta w}{2k} = 1 - \frac{\Delta}{6} \frac{Nw}{2k} \Gamma(\Delta)$$

W<1 absorption

w>1 gain

Self-Induced Transparency & Solitons

- ***** Example of a non-trivial application of the MBE's in the context of pulse propagation (highly dynamic, non-steady state behavior.
- (*) The pulse area theorem suggests a light pulse with the proper envelope will act as a 2π pulse. Thus, if the pulse is shorter than the excited state lifetime it may propagate without loss. Correct shaping may also allow propagation without changes in pulse shape.
- ***** See Lecture Notes, Slusher & Gibbs 1972.

Envelope: $\mathcal{E}(\frac{1}{2},t) = \frac{2\pi}{nT} \operatorname{sech}(\frac{\pi}{2}/T), \int_{0}^{\infty} \frac{1}{2} dt = 0$

Self-consistent solution with the the properties of a Soliton

$$\mathcal{E}(\frac{1}{2}, \frac{1}{2}) = \frac{2\hbar}{nT} \operatorname{sech}(\frac{5}{7})$$

$$\mathcal{U}(\frac{5}{7}) = 0$$

$$\mathcal{U}(\frac{5}{7}) = 2 \operatorname{Sech}(\frac{5}{7}) + \operatorname{tanh}(\frac{5}{7})$$

$$\mathcal{W}(\frac{5}{7}) = -1 + 2 \operatorname{Sech}(\frac{5}{7})$$

In the SVEA version of the Wave Eq.

$$\left(\frac{\partial}{\partial t} + \frac{1}{c} \frac{\partial}{\partial t}\right) \mathcal{E}(t,t) = \frac{ik}{\epsilon_0} N_{\mu} \mathcal{E}(u-i\upsilon)$$

Substitute solutions for ξ , M and N to get

$$\frac{2\hbar}{MT} \left(\frac{\partial}{\partial z} + \frac{1}{C} \frac{\partial}{\partial z} \right) \operatorname{Sech} \left(\frac{t - 2V}{T} \right) =$$

$$\frac{2\hbar}{MT} \left(\frac{-1}{VT} + \frac{1}{CT} \right) \left[-\operatorname{sech} \left(\frac{t - 2V}{T} \right) \tanh \left(\frac{t - 2V}{T} \right) \right] =$$

$$\frac{2\hbar N M^*}{\epsilon_0} \operatorname{Sech} \left(\frac{t - 2V}{T} \right) \tanh \left(\frac{t - 2V}{T} \right)$$

Solve for C/V to get

$$\frac{C}{V} = 1 + \frac{kNJNI^2}{2\varepsilon_0 k}CT^2 = 1 + \frac{1}{2}\alpha\beta CT^2$$

$$\alpha = \frac{kNJNI^2}{2\varepsilon_0 k\beta} = NT(0) \qquad \left(\begin{array}{c} \text{on-resonance} \\ \text{absorption coeff.} \end{array}\right)$$

where

Consider Na vapor, $\lambda = 589 \,\text{nm}$, $N = 10^{19} \,\text{m}^{-3}$, $T \sim 0 \,\text{K}$, and $\beta = 2 \,\text{TT} \times 4.9 \,\text{MHz}$ (completely opaque on res.)

Assuming
$$\sqrt{\frac{1}{2}} \stackrel{\triangle}{=} \stackrel{\triangle}{=} \sqrt{\frac{2}{a\beta c}} \sim 26pS \ll 16 ns !!$$
